Motivation

Global aerosol-climate models are associated with large biases in East Asia and China. Improving the emission inventory is necessary.

ACCMIP models v.s. AERONET AOD (Shindell et al., 2013)

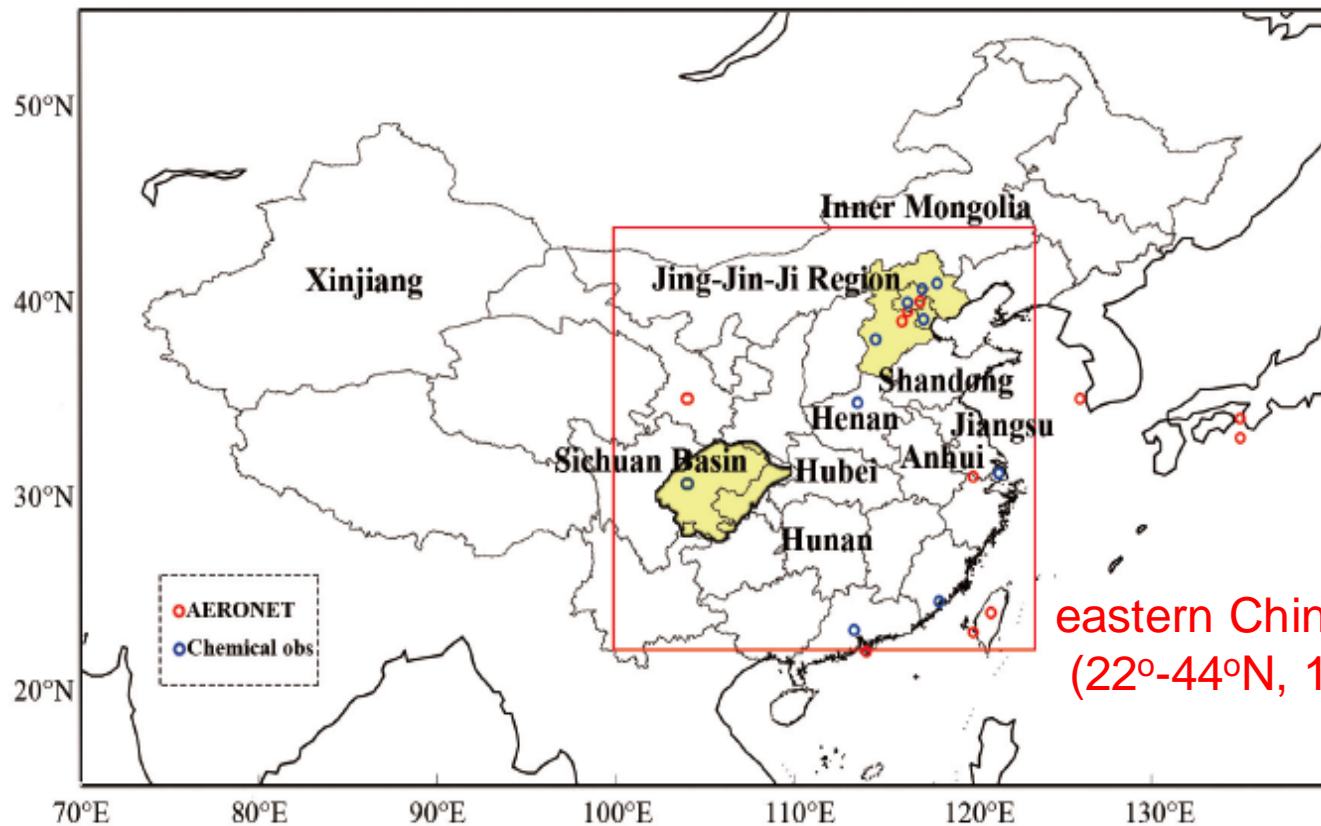

The emission inventory of aerosol and precursor gases

- Default: IPCC AR5 emission dataset
 - based on 2000 emission, update every 10 years
 - no seasonal variation
- Replacing with the new emission inventory
Multi-resolution Emission Inventory for China (MEIC)
(www.meicmodel.org) Tsinghua University, China
 - technology-based, rapid technology renewal, China's statistics
 - gridded data available in 2008, 2010, 2012. National averaged trend in 1990-2012
 - seasonal variation (monthly)

Model configuration

- MEIC emission in China and AR5 emission elsewhere.
- Nudged winds towards ERA-Interim in 2009.
- $0.9^\circ \times 1.25^\circ \times 30$ layers.
- 3-mode Modal aerosol Model (MAM3): Sulfate, black carbon (BC), Primary organics matter (POM), Secondary organic aerosol (SOA).
- Aerosol Direct Radiative Effect (ADRE): all-sky radiative fluxes difference between with and without aerosol scattering and absorption [Ghan, 2013].

Study area and observational sites

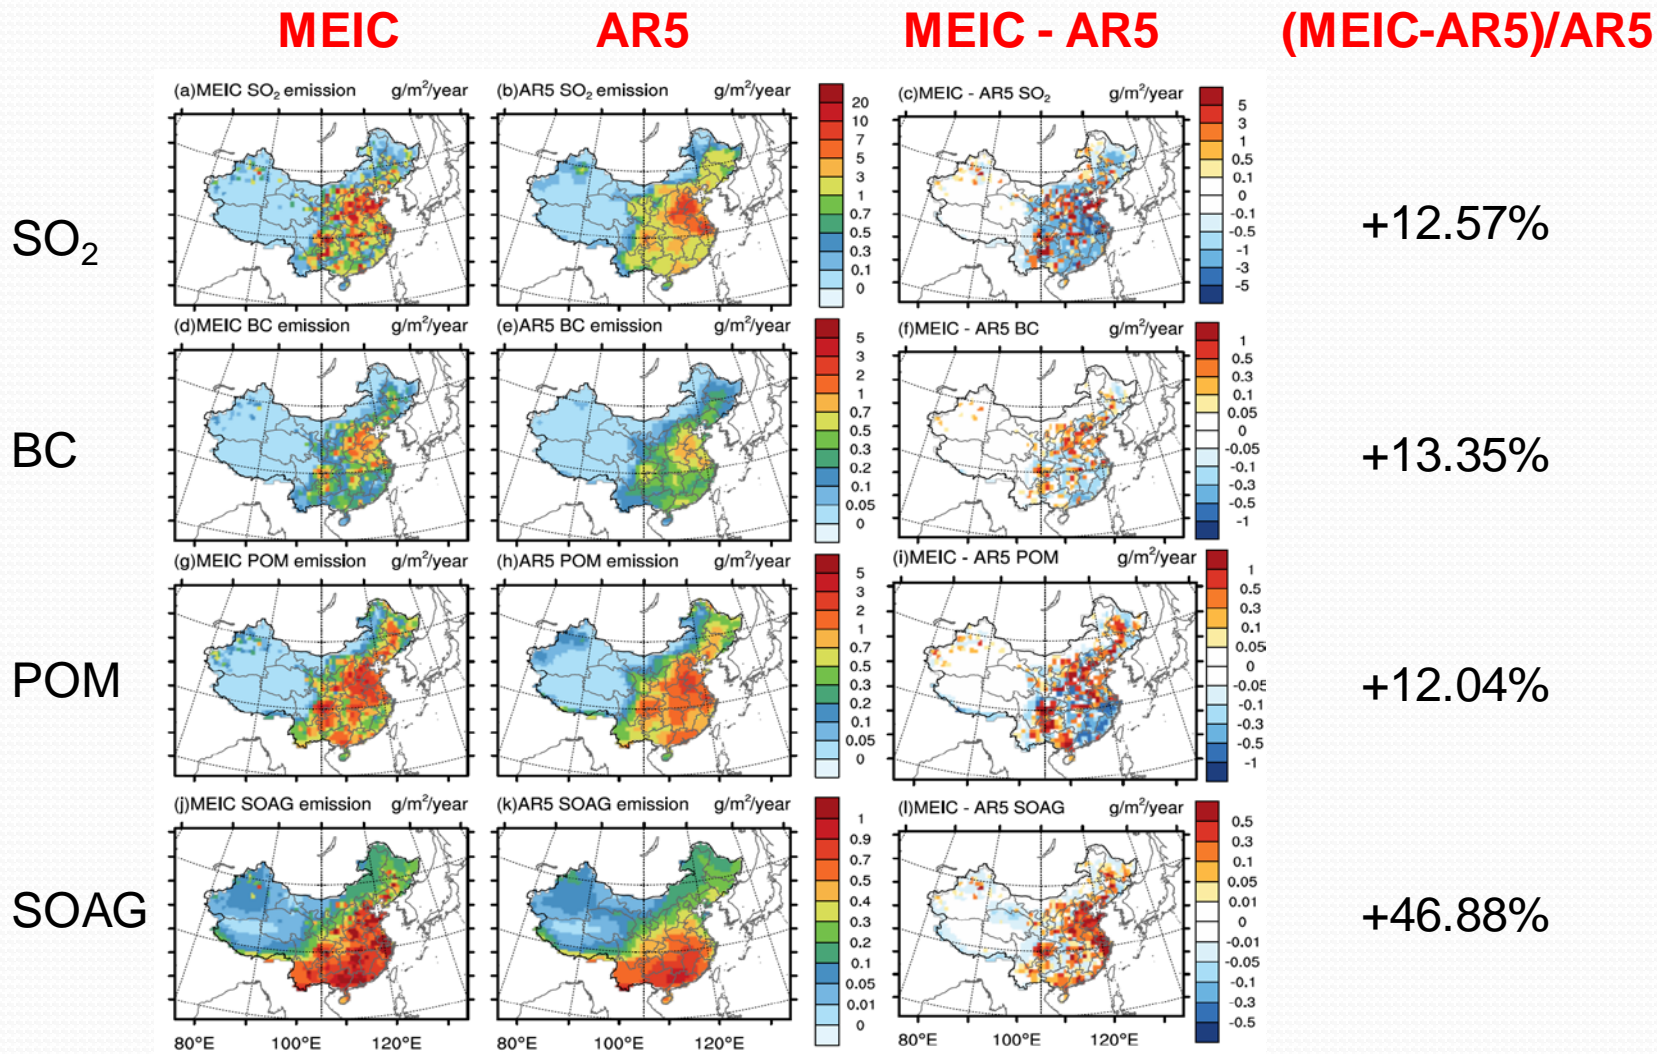

eastern China
(22°-44°N, 100°-124°E)

AOD and SSA retrievals: AeroNet, MODIS (Terra collection 6 deep blue), and MISR

Chemical observation of PM_{2.5} from literatures

Ground-based radiative effect observation: CSHNET and literatures

The MEIC is 12% to 47% higher than the AR5 dataset

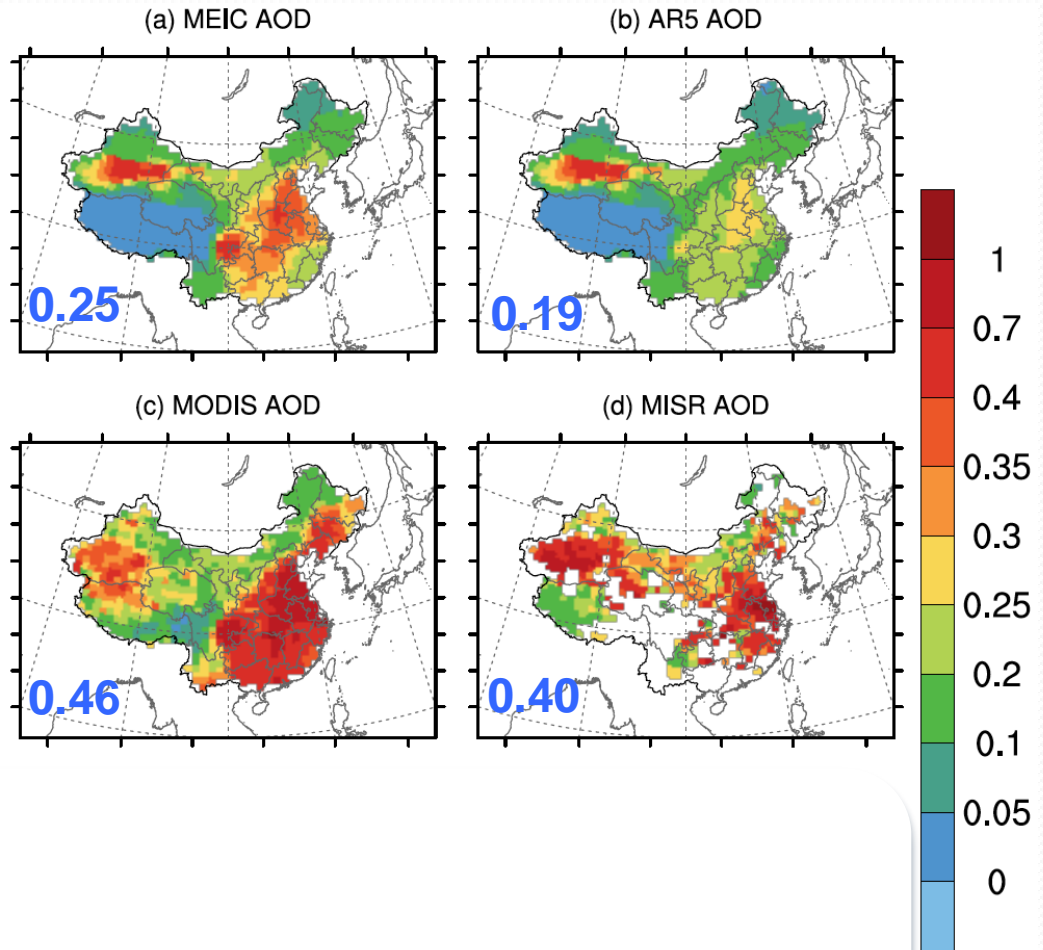

Seasonal variation of the emission inventories

The emission accounts for 22%-28% of the modeled AOD low biases in eastern China

CAM5 AOD

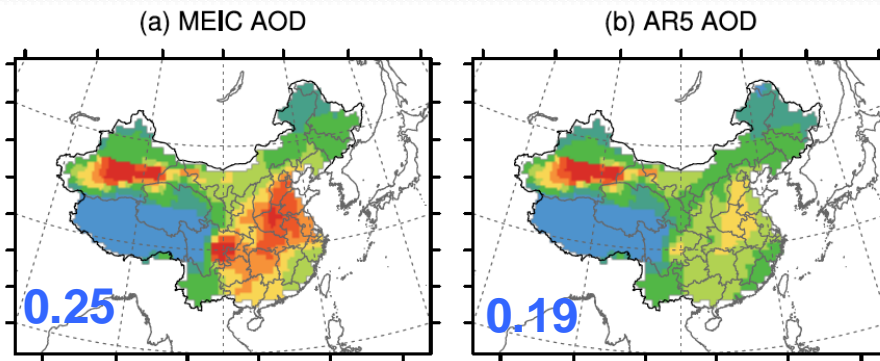

Satellite AOD

AOD is still underestimated by CAM5 with MEIC.

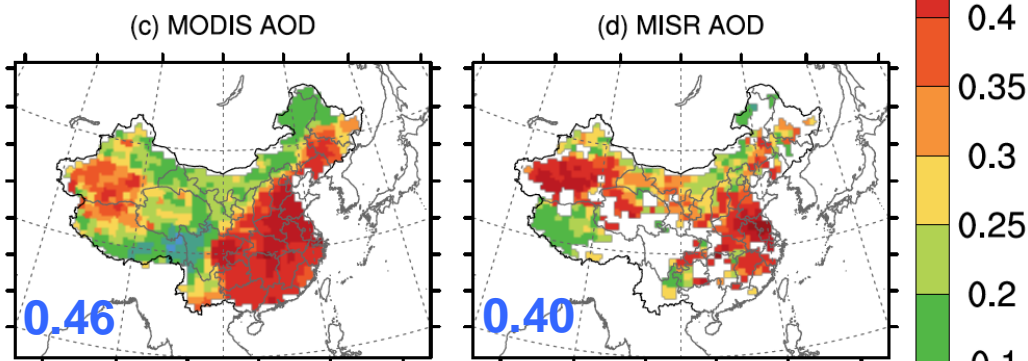

MEIC reproduces the spatial pattern of AOD

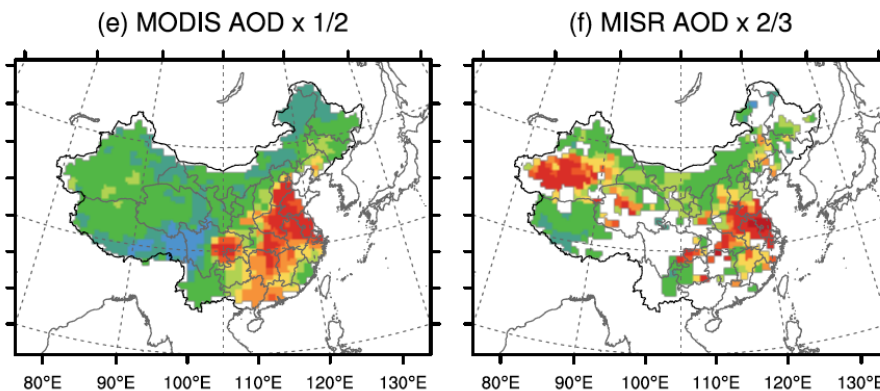

CAM5 AOD

Satellite AOD

MODIS x $\frac{1}{2}$,
MISR x $\frac{2}{3}$

Improved seasonal variation of AOD by MEIC

Sulfate aerosol
and POM

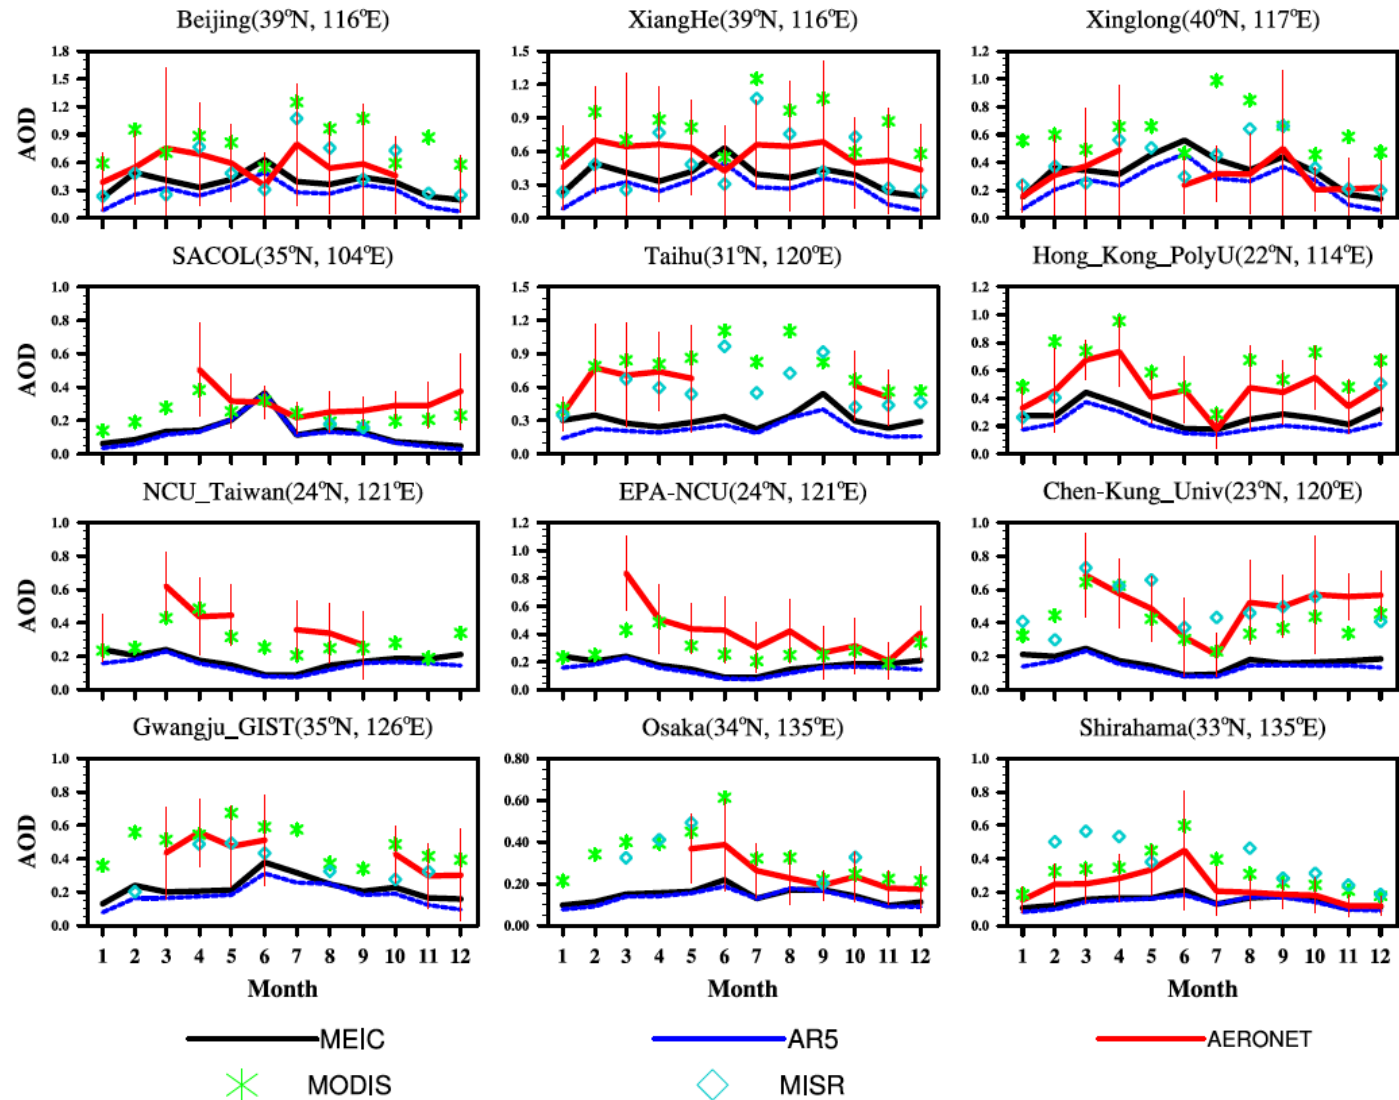

Missing summer maximum of AOD due to precipitation bias

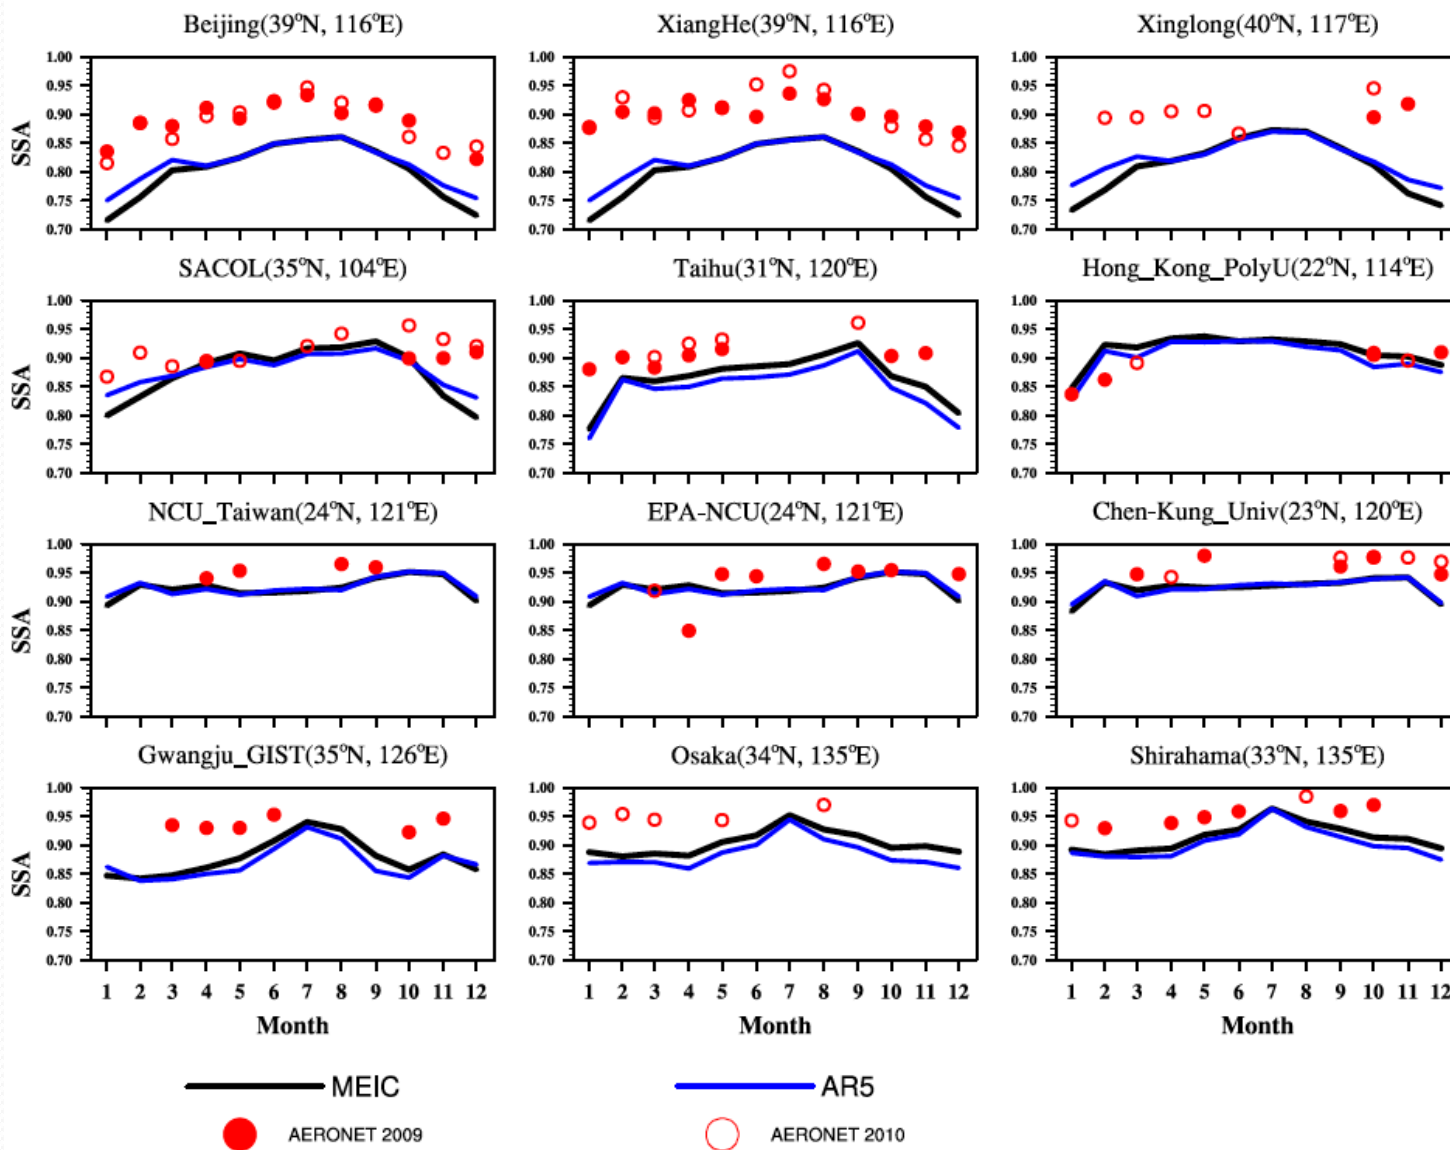

Modeled dust transport that is not observed by satellites

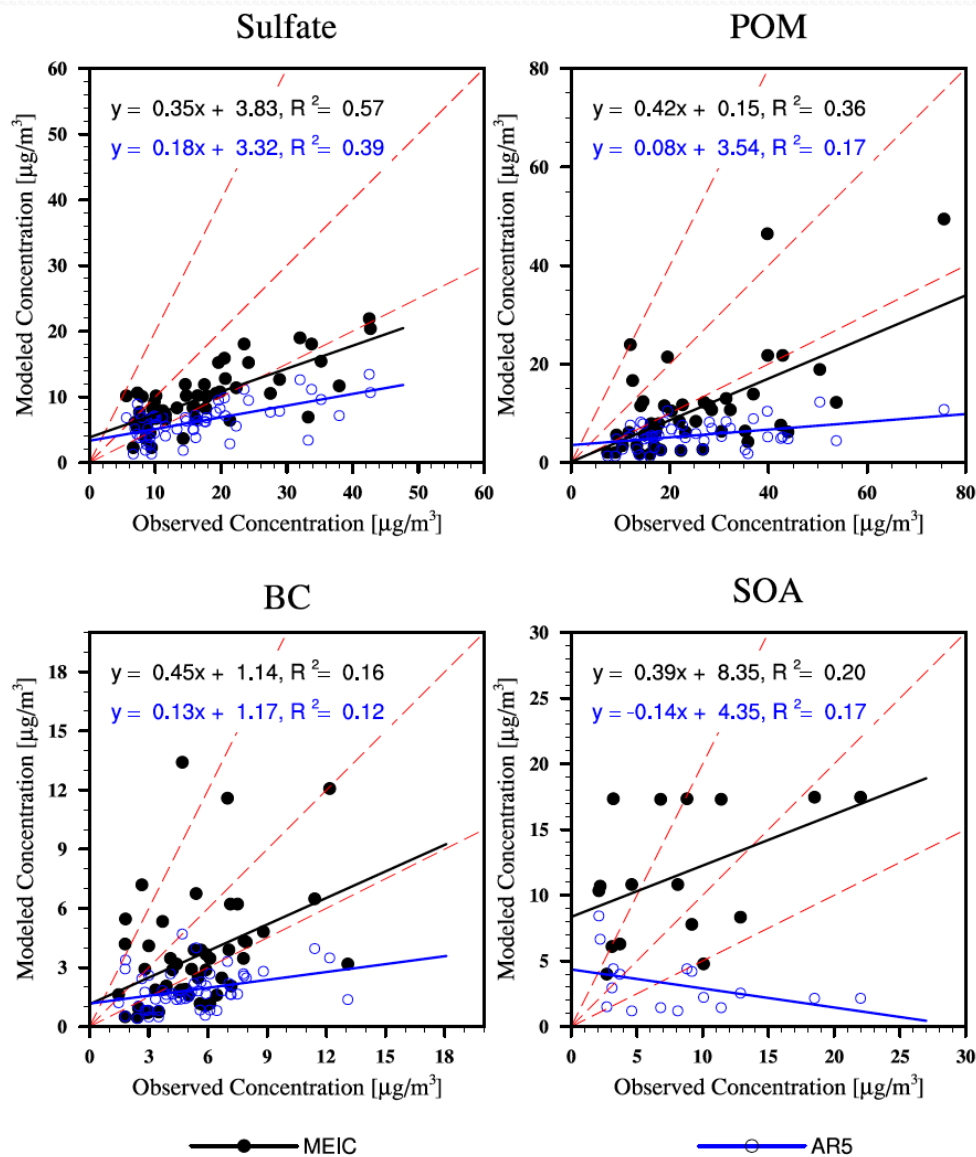

AOD modeled with MEIC agrees better with observations than the AR5 emissions

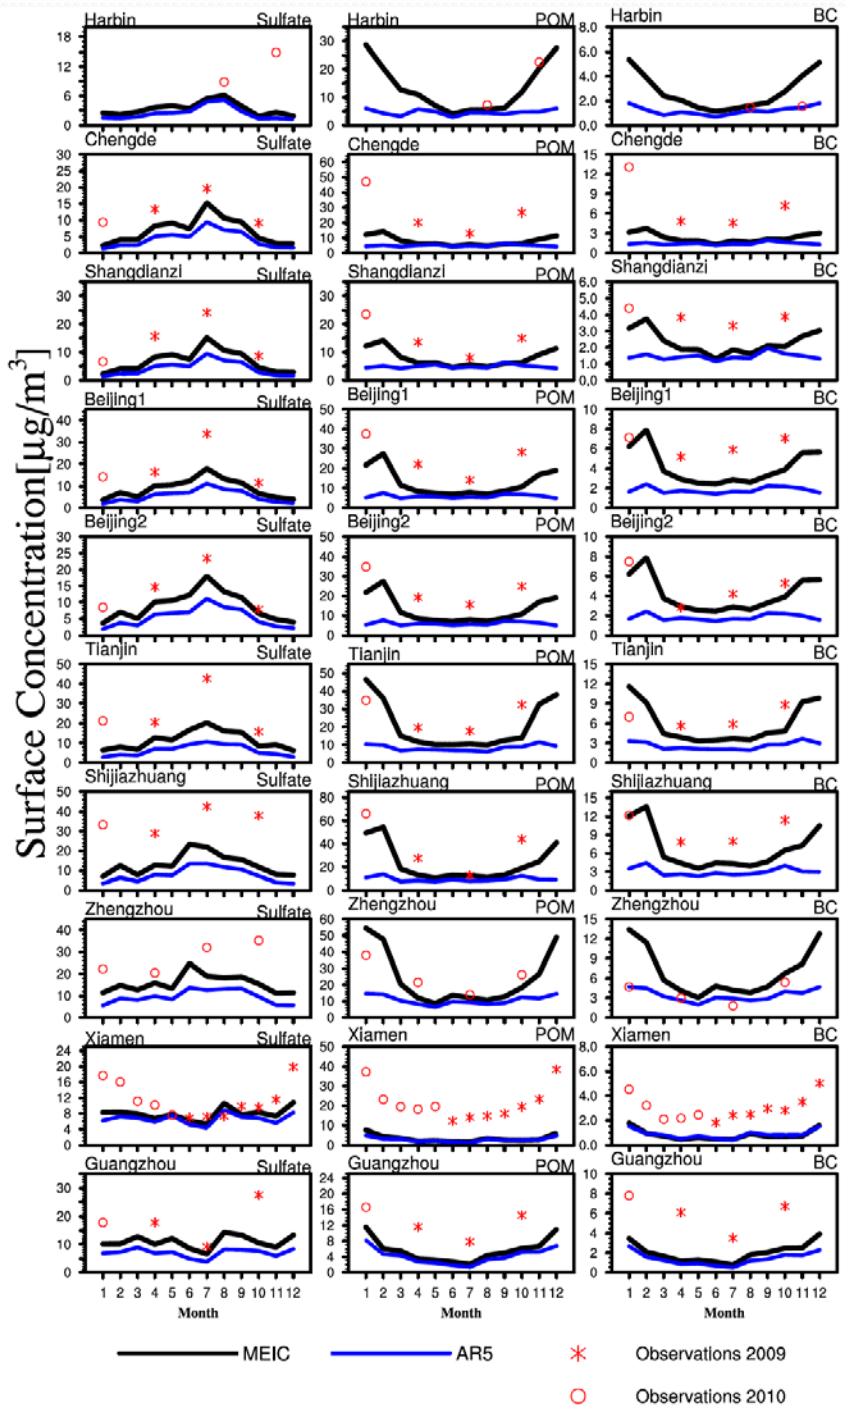

SSA modeled with MEIC and AR5 emissions compared with AERONET

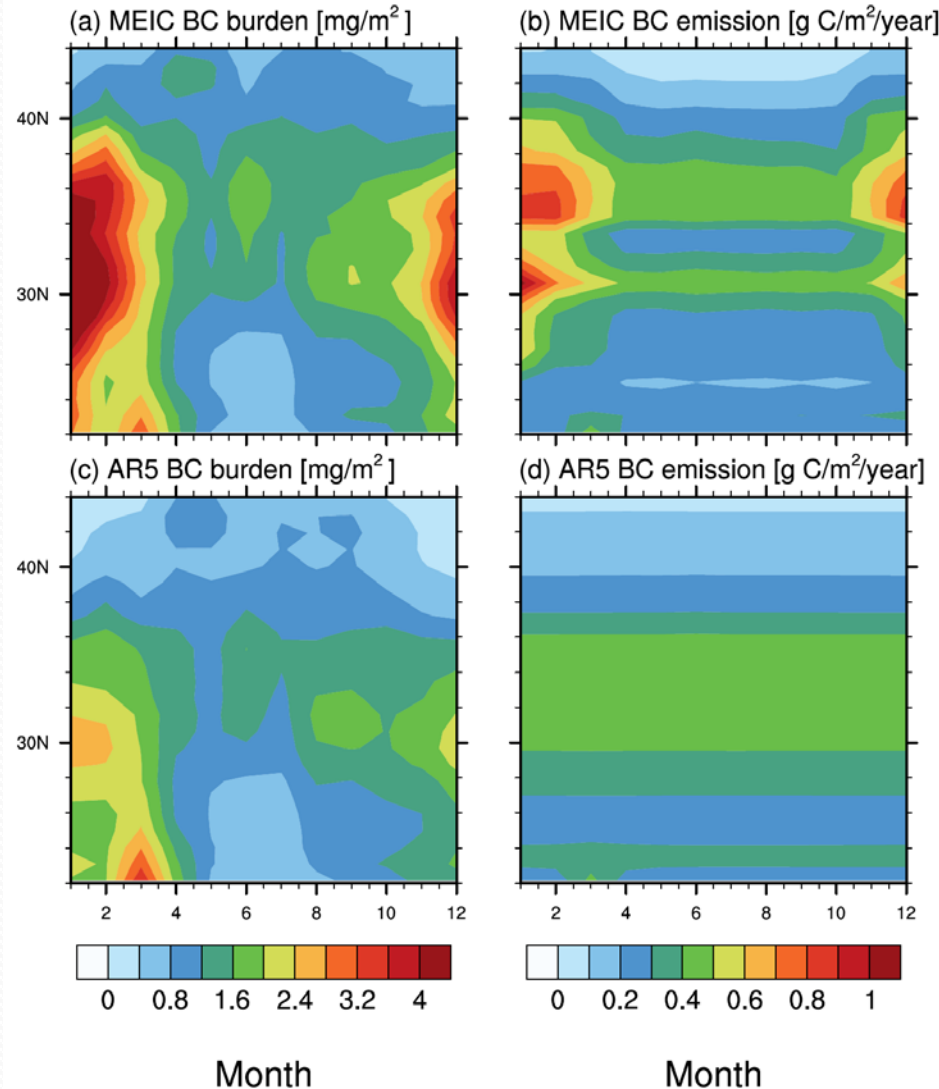

The simulated surface concentrations of all species are improved with MEIC

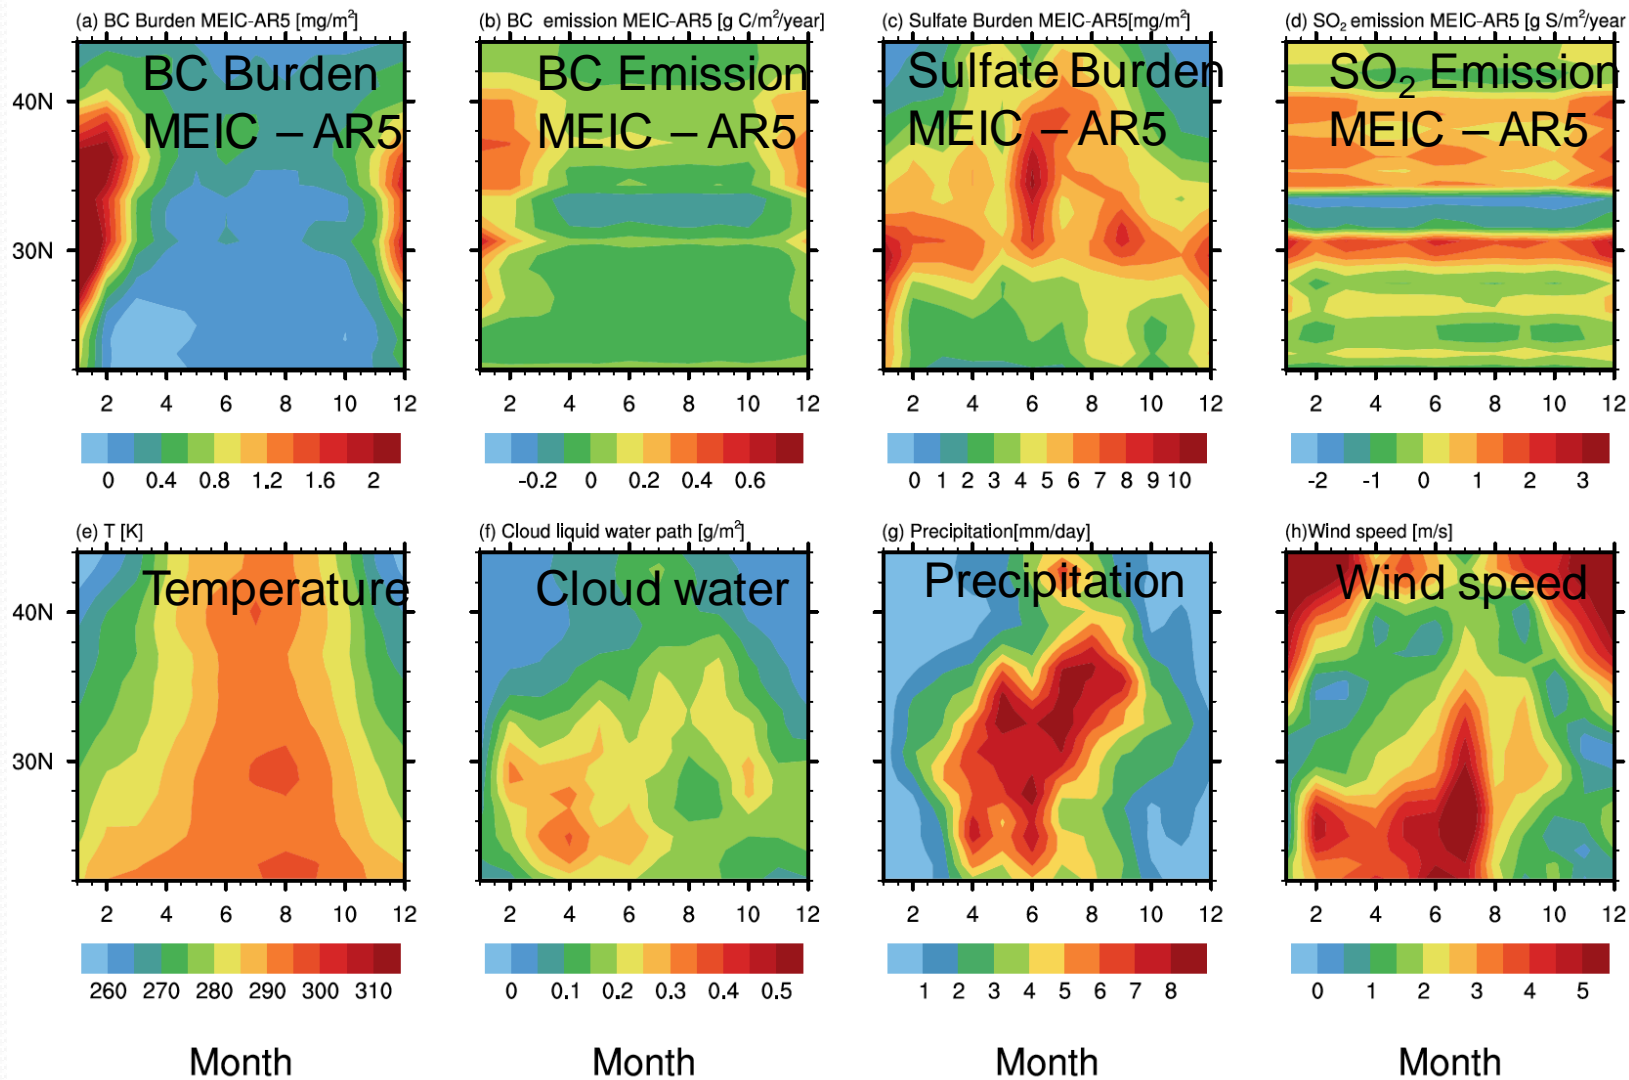

- The impact of emission on seasonal variation of sulfate is not obvious.
- MEIC emission significantly increases and improves the model simulations of BC and POM concentrations.

Seasonal variations of both the emission and meteorology play important roles

The impacts of emission on primary and secondary aerosols are different

MEIC estimate the averaged aerosol DRF at TOA, surface, and atmosphere to be -0.50, -12.76, 12.26 Wm^{-2} over eastern China

MEIC

AR5

MEIC - AR5

MEIC ADRE at TOA W/m^2

AR5 ADRE at TOA W/m^2

MEIC - AR5 ADRE at TOA W/m^2

With MEIC:
Enhanced cooling
effect **at TOA** by -
0.19 Wm^{-2}

MEIC ADRE at SFC W/m^2

AR5 ADRE at SFC W/m^2

MEIC - AR5 ADRE at SFC W/m^2

Enhanced cooling
effect **at surface**
by -2.42 Wm^{-2}

MEIC ADRE in ATM W/m^2

AR5 ADRE in ATM W/m^2

MEIC - AR5 ADRE in ATM W/m^2

Enhanced warming
effect **in the
atmosphere** by
2.23 Wm^{-2}

80°E 100°E 120°E

80°E 100°E 120°E

80°E 100°E 120°E

About 12% to 47% difference of the anthropogenic emission rates

About 30% difference of the total AOD of all species

About 22% difference of ADREs at the surface and in the atmosphere

About 63% of the ADRE at TOA

The impacts of the emission on AOD and ADRE are significant.

The impact of emission on ADRE of BC is more significant than the meteorological effects

MEIC

AR5

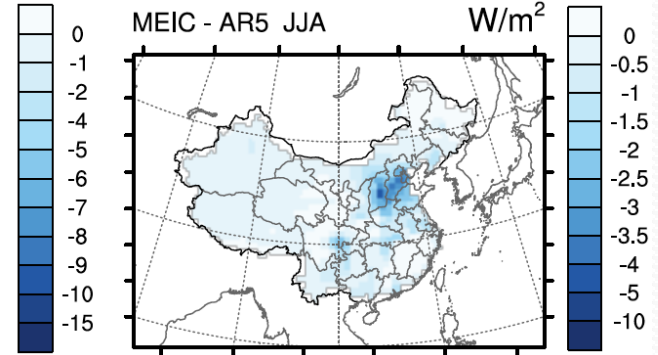

MEIC - AR5

summer

MEIC BC ADRE at SFC JJA W/m^2

AR5 BC ADRE at SFC JJA W/m^2

MEIC - AR5 JJA W/m^2

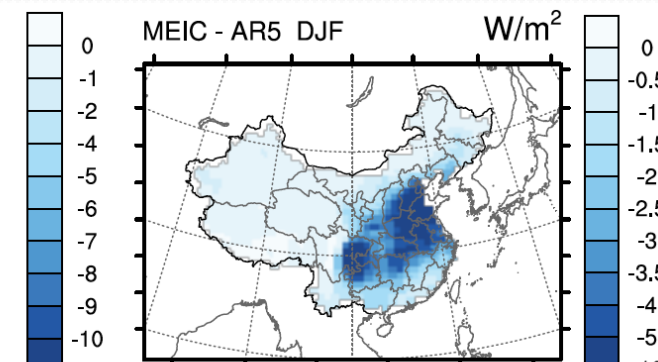

winter

MEIC BC ADRE at SFC DJF W/m^2

AR5 BC ADRE at SFC DJF W/m^2

MEIC - AR5 DJF W/m^2

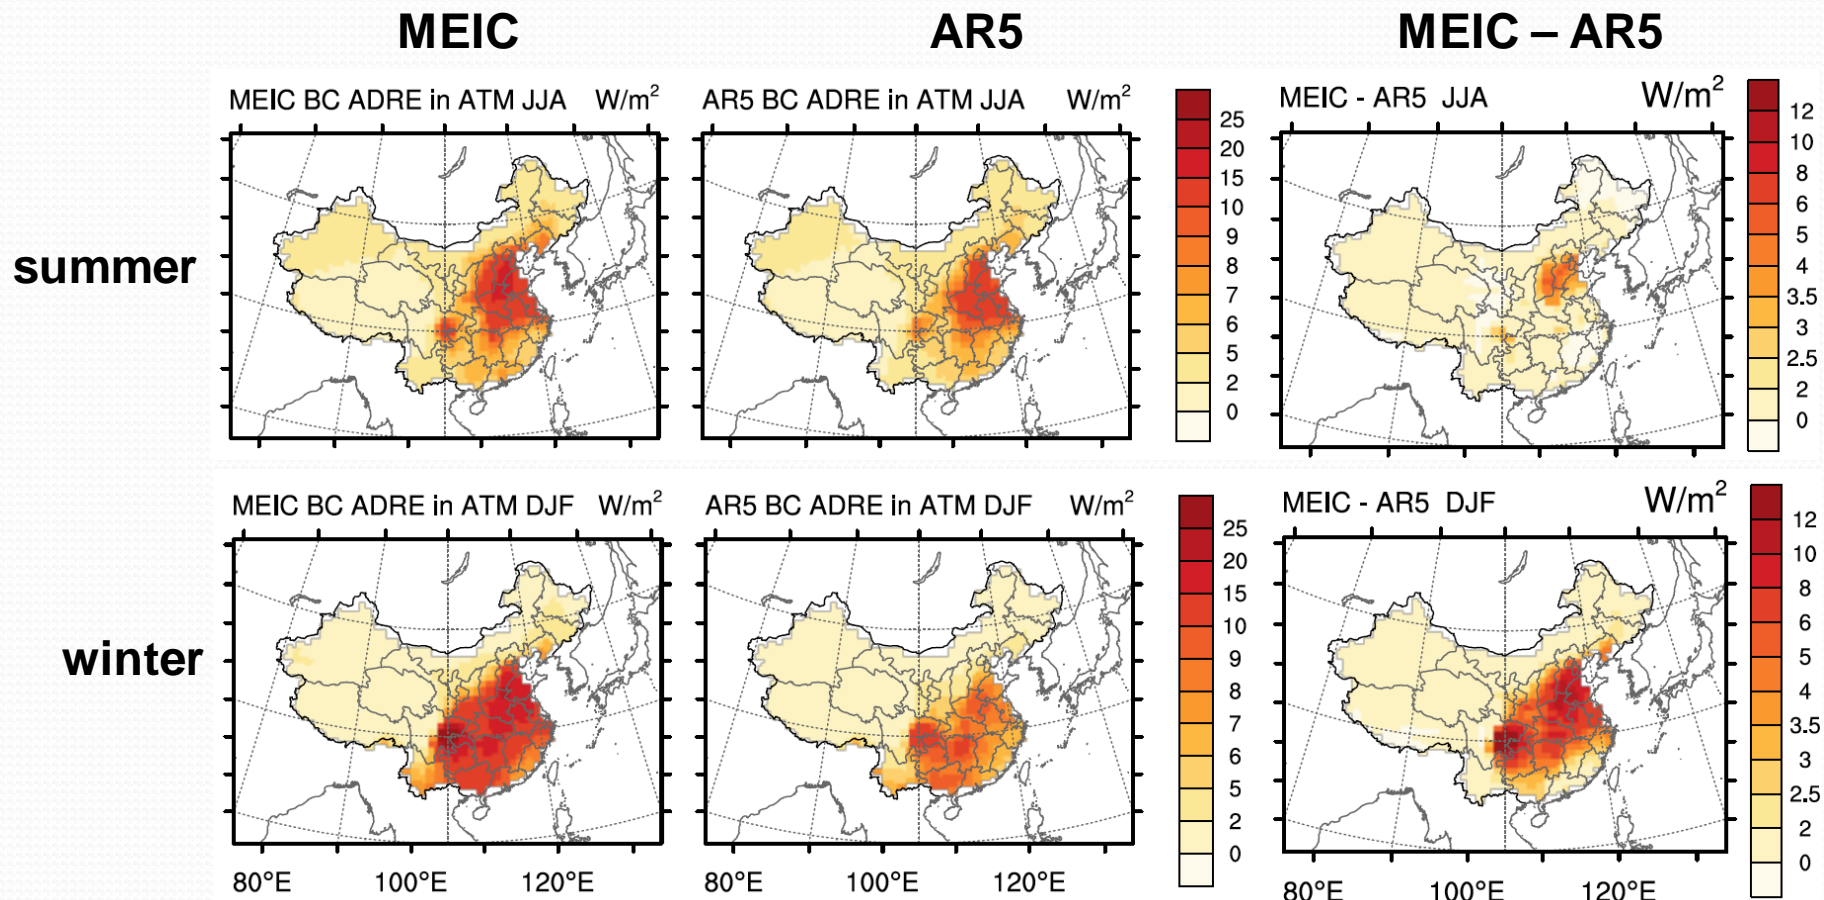

80°E 100°E 120°E

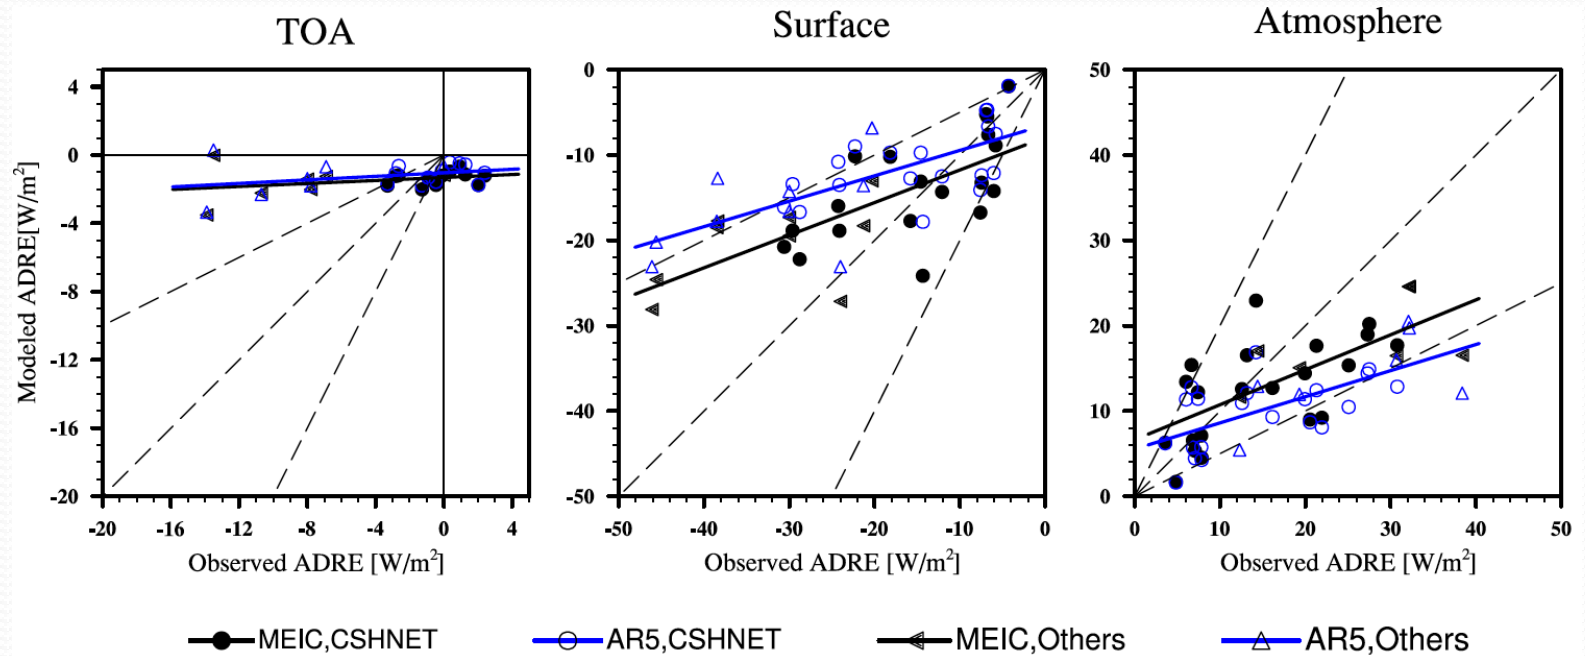

80°E 100°E 120°E

80°E 100°E 120°E

So does atmospheric warming due to BC

Modeled ADREs are improved with MEIC, but still underestimated

Observational data from Chinese Sun Hazemeter Network (CSHNET) (Xin et al., 2007; Li et al., 2010) and other literatures.

Summary

- This research highlights the critical importance of improving aerosol and precursor emissions for the modeling of aerosols and aerosol effects in East Asia.
- The new aerosol and precursor gases emission MEIC explains 22% to 28% of the AOD low-biases in eastern China in a GCM compared to satellite observations.
- The new emission inventory estimates the averaged aerosol direct radiative forcing at TOA, surface, and atmosphere to be -0.50, -12,76, and 12.26 W/m² over eastern China, which are enhanced by -0.19, -2.42, and 2.23 W m⁻² compared with the AR5 emission .
- Seasonal variation of MEIC emission determines the seasonal cycle of the primary aerosols, but not the secondary aerosols.
- In winter AR5 emission results in significantly lower cooling effect at the surface and warming in the atmosphere due to reduced black carbon emission than the MEIC emission.
