TOMS V8 Residue Definition

$$r_{\lambda} = -100 \left[\log \left(\frac{I_{\lambda}}{I_{331}} \right)_{meas} - \log \left(\frac{I_{\lambda}(R_{sfc})}{I_{331}(R_{sfc})} \right)_{calc} \right]$$

R_{sfc} is a *Lambert Equivalent effective surface reflectivity* value such that

$$(I_{331})_{meas} = (I_{331})_{calc}$$

R_{sfc} is assumed *wavelength independent*

Thus, the residue definition reduces to:

$$r_{\lambda} = -100 \log \left[\frac{(I_{\lambda})_{meas}}{(I_{\lambda}(R_{sfc}))_{calc}} \right]$$

Calculation of Effective Surface Reflectivity

$$R_{sfc} = \frac{I_{331_{meas}} - I_{331_{Ray}}}{T_{331_{Ray}} + S_{331_{Ray}} (I_{331_{meas}} - I_{331_{Ray}})}$$

Residues are calculated at all the TOMS wavelengths.

Residues at $\lambda < 331$ nm are positive

Residue at 331 nm is zero by definition

Residues at $\lambda > 331$ nm are negative

The TOMS V8 Aerosol Index is the negative value of the 360 nm residue

$$AI = -r_{360}$$
